Contents

- Motivation
- Epipolar Geometry
- Epipolar Elements
- Point Correspondences

Motivation

Given x' in the first image, **find** the corresponding point x'' in the second image.

- Coplanarity constraint
- Intersection of two corresponding rays
- The rays lie in a 3D plane

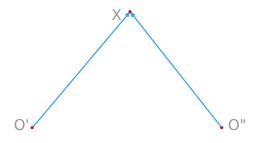

Figure 1: Coplanarity

Epipolar Geometry

- describe geometric relations in image pairs
- efficient search and prediction of corresponding points
- search space reduced from 2D to 1D

Epipolar Geometry

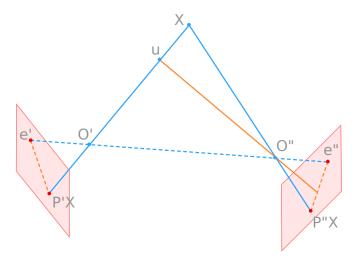

Figure 2: Epipolar Geometry

Epipolar Geometry

Epipolar elements:

- epipolar axis $\mathcal{B} = (O'O'')$
- epipolar plane $\mathcal{E} = (O'O''X)$
- epipoles e' = (O'')', e'' = (O')''
- epipolar lines $\mathcal{L}'(X) = (O''X)', \mathcal{L}''(X) = (O'X)''$

We can also write the **epipoles** as:

$$e' = (O'O'') \cap \mathcal{E}', \quad e'' = (O'O'') \cap \mathcal{E}''$$

And the epipolar lines as:

$$\mathcal{L}'(X) = \mathcal{E} \cap \mathcal{E}', \quad \mathcal{L}''(X) = \mathcal{E} \cap \mathcal{E}''$$

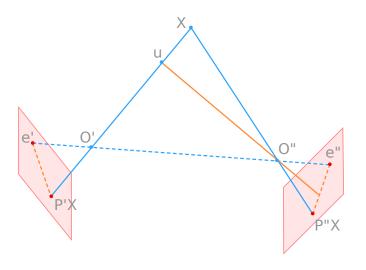

Figure 3: Epipolar Geometry

In the Epipolar Plane

Assuming a distortion free lens:

- The projection centres O' and O''.
- The observed point X.
- The epipolar lines, $\mathcal{L}'(X)$ and $\mathcal{L}''(X)$.
- The epipoles, e' and e''.
- The image points x' and x''.

In the Epipolar Plane

- The projection centres O' and O''.
- The observed point X.
- The epipolar lines, $\mathcal{L}'(X)$ and $\mathcal{L}''(X)$.
- The epipoles, e' and e''.
- The image points x' and x''.

All lie in the epipolar plane \mathcal{E} .

Predicting Point Correspondence

Task: Predict the location of x'' given x'.

- For the epipolar plane $\mathcal{E} = (O'O''X)$
- The intersection of $\mathcal E$ and the second image plane $\mathcal E''$ yields the epipolar line $\mathcal L''(X)$
- The corresponding point x'' lies on that epipolar line $\mathcal{L}''(X)$.
- Search space is reduced from 2D to 1D.

Computing the Elements of Epipolar Geometry

Computing the Elements of Epipolar Geometry

- We described the important elements geometrically.
- We will compute them using the projection matrices and the fundamental matrix.

Epipolar Axis

The direction of the epipolar axis can be derived directly from the projection centres.

$$b = X_{O'} - X_{O''}$$

The vector *b* is *homogeneous* and the equation expresses that we know only the *direction*, **not** the *length*.

Image points lie on the epipolar lines.

$$x' \in \mathcal{L}', \quad x'' \in \mathcal{L}''$$

For x':

$$x^{'T}\mathcal{L}'=0$$

For x':

$$x^{'T}\mathcal{L}'=0$$

We can exploit the coplanarity constraint for x' and x'':

$$x'^T \underbrace{\mathcal{F}x''}_{\mathcal{L}'} = 0$$

We can exploit the coplanarity constraint for x' and x'':

$$x'^T \underbrace{\mathcal{F}x''}_{\mathcal{L}'} = 0$$

$$\mathcal{L}' = \mathit{Fx}''$$

The same for x'':

$$\mathcal{L}^{"T}x"=0$$

We can exploit the same constraint $x^{'T}Fx^{\prime\prime}=0$ and obtain:

$$\mathcal{L}^{''T} = x^{'T}F$$

We can exploit the same constraint $x'^T F x'' = 0$ and obtain:

$$\mathcal{L}^{''T} = x^{'T}F$$

$$\mathcal{L}^{''} = F^T x^{'}$$

Image points lie on the epipolar lines, $x' \in \mathcal{L}'$ and $x'' \in \mathcal{L}''$.

- we can exploit the coplanarity constraint $x'^T F x'' = 0$.
- which is valid if:

$$\mathcal{L}' = Fx'' \quad \mathcal{L}'' = F^Tx'$$

Epipoles

The epipoles are the projection of the camera origin onto the other image.

- Both can be computed using the projection matrices.

Epipoles

The epipoles are the projection of the camera origin onto the other image.

Both can be computed using the projection matrices.

$$e' = P'X_{O''}$$
 $e'' = P''X_{O'}$

Epipoles

The epipole is the *intersection* of **all** the epipolar lines in an image.

$$\forall \mathcal{L}' : e^{'T} \mathcal{L}' = 0 \quad \forall \mathcal{L}'' : e^{''T} \mathcal{L}'' = 0$$

Summary

- We assumed an uncalibrated camera.
- We discussed Epipolar geometry and epipolar elements.
- Epipolar geometry reduces the correspondence search from 2D to 1D.
